

Saturday, June 14, 2025 11:08 AM

1. Load a CSV file and print the first 5 rows.
2. Print the shape and data types of the DataFrame.
3. Load a JSON file into a Pandas DataFrame.
4. Read a Parquet file and check for null values.
5. Display summary statistics for a DataFrame using ``describe()``.

1. Drop rows with missing values from a DataFrame.
2. Fill missing values with the column mean.
3. Remove duplicate rows from a DataFrame.
4. Convert a column to datetime format.
5. Change the data type of a column from float to int.

1. Select rows where a column's value is greater than 100.
2. Filter a DataFrame where a string column contains the word "data".
3. Select only specific columns from the DataFrame.
4. Use `.loc` and `.iloc` to access specific rows and columns.
5. Filter rows using multiple conditions (AND/OR).

1. Group data by a column and calculate the mean.
2. Group by multiple columns and calculate the sum.
3. Count the number of unique values in a group.
4. Use `agg()` to apply multiple aggregations.
5. Calculate the average of a column after grouping and sort the result.

1. Merge two DataFrames using a common column.
2. Perform an inner join on two DataFrames.
3. Perform a left join and fill missing values with 0.
4. Concatenate two DataFrames vertically.

- ## Exporting Data

- ## Practice Resources

- ## DataFrame DRILL

1. Load a CSV file into a DataFrame.
2. Check the first 5 rows of the DataFrame.
3. Get the shape of the DataFrame (rows, columns).
4. Get summary statistics (mean, median, mode, std) of numerical columns.
5. Get the data types of each column.
6. Check for missing values in each column.
7. Rename a column in the DataFrame.
8. Filter the DataFrame to get rows where a column value is greater than a certain number.
9. Select specific columns from the DataFrame.
10. Drop a column from the DataFrame.
11. Apply a transformation to a column (e.g., multiply each value by 2).
12. Add a new column based on an operation on existing columns.
13. Group the data by a categorical column and get the mean of each group.
14. Sort the DataFrame based on a specific column.
15. Merge two DataFrames on a common column.
16. Join two DataFrames using an index.
17. Apply a function to each element in a column using `.apply()`.
18. Create a new DataFrame by filtering rows based on multiple conditions.
19. Convert a column from string to a numeric type.
20. Save the modified DataFrame to a new CSV file.
